# Newton gravitational constant G

### • G = $6.674 \times 10^{-11} \text{ m}^3 \text{kg}^{-1}\text{s}^{-2}$

• Best precision (red):  $1 \times 10^{-5}$ (Li et al. 2018, Nature, 560, 582)

Constraining  $\dot{G}$  with millisecond pulsars

• The time variability of G (Damour et al. 1988)

- c: light speed.
- *μ*: *total proper motion* of the pulsar in a binary system.
- $D_k$ : The kinematic distance measured with the timing parameters ( $P_b$ ,  $\dot{P}_b$ ,  $\mu$ ).
- $D_{\pi}$ : the distance measured with the annual parallax  $\pi$ .

# PSR J0437-4715

- The brightest millisecond pulsar at radio
- The nearest millisecond pulsar
- One of a few extremely stable pulsars
- The most accurate distance measurements to a pulsar

Timing:  $D_k = 157.0 \pm 2.4 \text{ pc} (100 \ \mu as, 1.5\%)$ --Verbiest et al. (2008) with Parkes64 at L band.

VLBI:  $D_{\pi} = 156.3 \pm 1.3 \text{ pc} (\pi = 6396 \pm 54 \text{ } \mu\text{as})$ 

 $\frac{G}{G} = (-5 \pm 26) \times 10^{-13} \text{ yr}^{-1}$  (95% confidence)

Lunar laser ranging:  $(4 \pm 9) \times 10^{-13} \text{yr}^{-1}$  (Williams et al. 2004)

--Deller et al. (2008) with the LBA at 8.4 GHz.

Timing:  $D_k = 156.79 \pm 0.25 \text{ pc} (10 \ \mu as, 0.16\%)$ 

--Reardon et al. (2016) with Parkes64 at L band.

# Discovery of two in-beam sources

SNR~7 for R1 and R2. Probability of the good luck: ~1/1000. Setup: LBA+KM, 1 Gbps data rate & 6 hour on-source time. Published by Li et al. (2018) in MNRAS.

# Flat spectra & stable flux density => Most likely extragalactic radio cores

## To reach an accuracy of <10 $\mu$ as for the $\pi$

- The tiny separations allows the differential calibration to work extremely clean. The remaining systematic positional error:  $\leq 4 \mu as$  (Deller et al. 2018).
- The stable radio luminosities indicate that they are likely stationary reference points.
- The relative astrometry between R1 and R2 also helps us to quantitively estimate the systematic positional errors caused by the radio core jitter.
- The flat spectra make broad-band VLBI observations become particular useful in improving the image SNRs.

# ~10x better astrometry accuracy with respect to an 1mJy in-beam FIRST source

Yang et al. 2016, MNRAS

## The ongoing astrometry observations with LBA+HhT6KmWa at 6.7 GHz

IF

Phase vs time of 6mJy PSR J0437–4715 data in V558B. Fringes are clearly seen on all the baselines to the ATCA in the two epochs.

# SUMMARY

- Two in-beam sources extremely close to PSR J0437–4715 were found.
- It is quite promising for the ongoing VLBI astrometry observations at 6.7 GHz to gain an accuracy of <=25  $\mu$ as for the  $\pi$ .
- No known bottlenecks on achieving extremely high parallax accuracy of <10  $\mu \rm as$  in the near future.
- Final goal: A factor of ~10 improvement on the constraint of  $\frac{G}{c}$ .
